Healthcare AI Hackathon

AI Triage Predictor

Smarter Emergency Care, Starting at Your Fingertips

Aly Mooltazeem (V00962689)
Oliver Ware (UVic Alumni)

Team 911

The Real Problem

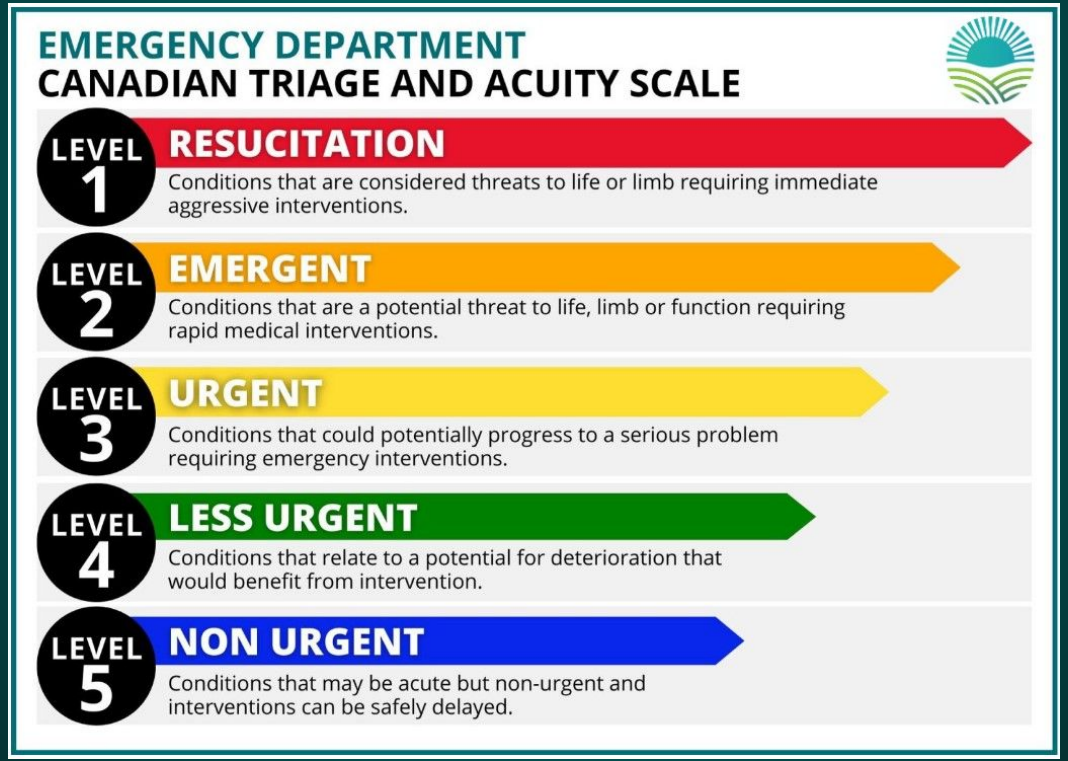
Canada's ER System Is Under Pressure

- 1 family doctor for every ~1,000+ Canadians
- Average ER wait times can exceed 4–6 hours
- Patients arrive without knowing how serious their condition is
- Overcrowding leads to missed urgencies and unnecessary visits

What if patients could understand their urgency level before they even enter the hospital?

What is CTAS?

The Scale That Decides Who Gets Help First



OUR SOLUTION

RECAP

A Virtual Triage Assistant Powered by AI

1 NLP Processing

User types their symptoms in plain English without worrying too much about syntaxes.

2 CTAS Output

AI analyzes input against a real clinical dataset (chief complaints → CTAS labels)

3 Responsive UI

Returns a predicted triage level instantly

4 Next steps

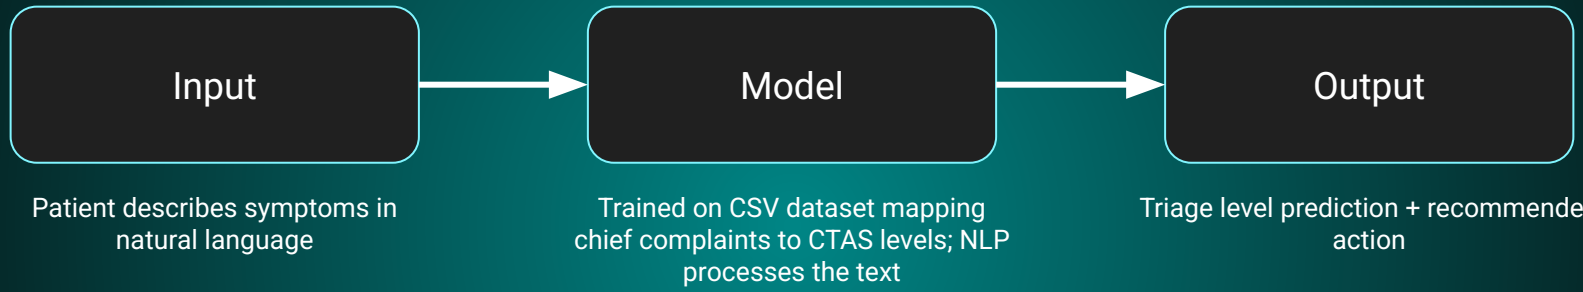
Guides the user on urgency and next steps, e,g. making appointments to nearest and most convenient ERs

Grounded in Real Clinical Data

- Large CSV dataset of real triage records
- Features include: chief complaint (plain English), vital signs indicators, final CTAS rating
- Model learns the language patterns clinicians use to assign urgency

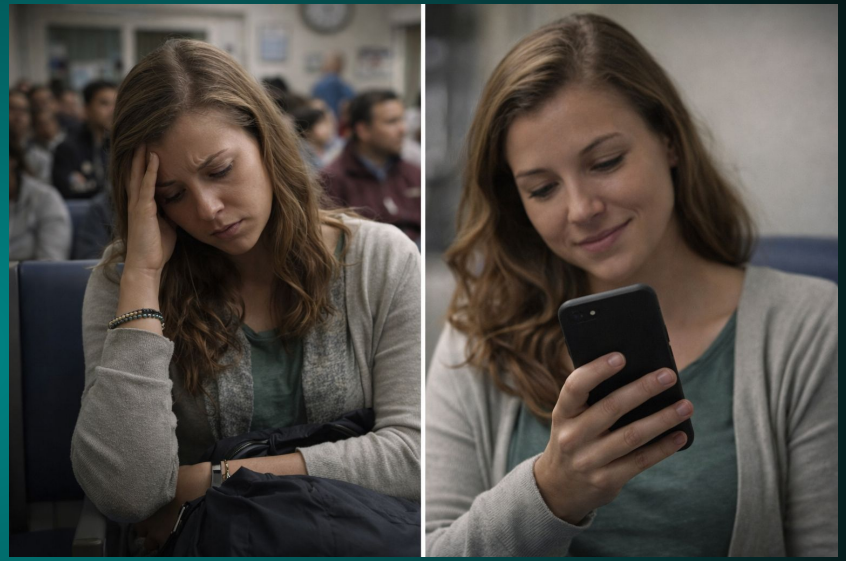
Under the Hood

How it works?



WHY IT MATTERS?

- Reduces unnecessary ER visits for low-urgency cases
- Helps high-urgency patients self-identify and act faster
- Lowers patient anxiety by giving clear, actionable guidance
- Potential to reduce strain on Canada's overburdened healthcare system



Future Considerations: Where This Goes Next

Appointment booking tied to triage level — urgent cases get earlier slots
Hospital routing — recommends the nearest ER with the shortest wait time
Crowding awareness — live data integration to redirect patients from overwhelmed ERs
Multilingual support — critical for diverse Canadian communities
